@RestController

- @Controller + @ResponseBody.
- It indicates that the class's methods return domain objects rather than views and that the results should be written directly to the HTTP response body.

@RequestMapping

- define a common path prefix for all the methods inside that controller.
- It can be applied at the **class and/or method** level to define URL patterns and specify request methods.

```
@RestController
@RequestMapping("/products")
public class ProductController {

    @RequestMapping(method = RequestMethod.GET)
    @ResponseBody
    public String getProducts() {
        return "List of Products";
    }
}
```

@GetMapping, @PostMapping, @PutMapping, @DeleteMapping, @PatchMapping

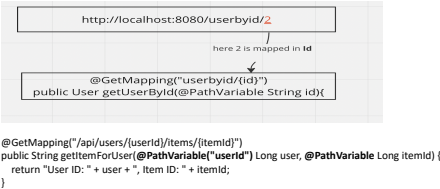

- Specialized shortcut annotations introduced in Spring 4.3
- Simplify the mapping for specific HTTP methods (GET, POST, PUT, DELETE, PATCH).

```
@RestController
public class UserController {

    @PostMapping("/api/users")
    public User createUser(@RequestBody User user) {
        // ... logic to save the user ...
        return user;
    }
}
```

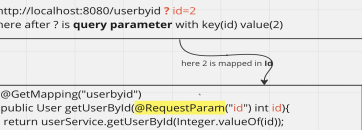

@PathVariable

Extract data from the URL path (curly bracket {}) se delcare karte hai {}

@RequestParam

- used to retrieve query parameters, anything after ? in the URL.
- is used to extract data from the **query parameters** in the request URL.
- Query parameters are the key-value pairs that appear after the ? in a URL

@RequestBody

- Binds the HTTP request body to a Java object, using message converters.
- Ideal for transferring data (typically JSON or XML) in requests such as POST or PUT.
